# A SMOOTH FAMILY OF CANTOR SETS 

IGNACIO GARCIA

#### Abstract

We show that the Cantor set $C_{p}$ associated to the sequence $\left\{1 / n^{p}\right\}_{n}, p>1$, is a smooth attractor. Moreover, it is smoothly conjugate to the $2^{-p}$-middle Cantor set. We also study the convolution of Hausdorff measures supported on these sets and the structure and size of the sumset $C_{p}+C_{q}$.

## 1. Introduction and statement of main results

1.1. Introduction. A Cantor set is a compact, perfect and totally disconnected set in some topological space. We deal with Cantor sets in the real line with the usual topology.

There is a way to construct zero Lebesgue measure Cantor sets that consists in successively removing gaps, that is, bounded open intervals, from an initial closed interval; the construction is done by steps and the lengths of the removed gaps are prescribed by the values of a positive and summable sequence. The precise definition, which appeared in [BT54], is given in Section 2. For example the 'classical' middle- $r$ Cantor set $A_{r}, 0<r<1 / 2$, that is defined by

$$
A_{r}=\left\{(1-r) \sum_{j \geq 0} a_{j} r^{j}: a_{j} \in\{0,1\}\right\},
$$

is the one associated to the sequence $\left\{\xi, r \xi, r \xi, r^{2} \xi, r^{2} \xi, r^{2} \xi, r^{2} \xi, \ldots\right\}$, where $\xi=1-2 r$. Here, the ratio between the lengths of the gaps of consecutive steps is constant, which reflects the 'linearity' of the set. Note that $A_{1 / 3}$ is the classical ternary Cantor set.

We will mainly focus on the $p$-Cantor set $C_{p}$, that is defined through the above construction using the sequence $\left\{1 / n^{p}\right\}_{n}, p>1$. At any fixed step the removed gaps have strictly decreasing lengths, which reflects the nonlinear nature of this set. Despite its nonlinearity, this is a family of well behaved Cantor sets, since in [CMPS05] and [GMS07] it is shown that $0<\mathcal{H}^{1 / p}\left(C_{p}\right)<P_{0}^{1 / p}\left(C_{p}\right)<+\infty$, where $\mathcal{H}^{t}$ and $P_{0}^{t}$ denotes the $t$-dimensional Hausdorff measure and packing premeasure respectively; in particular, $\operatorname{dim} C_{p}=\overline{\operatorname{dim}}_{B} C_{p}=1 / p$, where dim and $\operatorname{dim}_{B}$ denote the Hausdorff and upper Box dimensions. See the book of Mattila [Mat95] for the definitions of these measures and dimensions. In this article we discover further properties of this family of Cantor sets, showing that it is closely related to the family of middle- $r$ Cantor sets and so it can be viewed as a nonlinear version of the classical linear case.
1.2. Statements of main results. Let us recall that an iterated function system (IFS) is a finite set $\left\{f_{0}, \ldots, f_{n}\right\}$ of self maps defined on a nonempty closed subset $X \subset \mathbb{R}$ such that each $f_{i}$ is strict contraction, that is, there is a constant $0<c<1$ such that

$$
\left|f_{i}(x)-f_{i}(y)\right| \leq c|x-y|, \quad \forall x, y \in X, \quad i=0, \ldots, n
$$

Key words and phrases. dynamically defined Cantor sets, Sums of Cantor sets, convolution of measures.

Hutchinson [Hut81] proved that to each IFS one can associate an unique nonempty compact invariant set, that is, a set $K$ that verifies

$$
K=\bigcup_{i=0}^{n} f_{i}(K)
$$

Moreover, given a probability vector $\left(p_{0}, \ldots, p_{n}\right)$ with $\sum_{i=0}^{n} p_{i}$ and $p_{i} \in(0,1)$, there is a unique probability measure $\mu$ supported on $K$, called invariant measure, such that

$$
\begin{equation*}
\mu(A)=\sum_{i=0}^{n} p_{i} \mu\left(f_{i}^{-1}(A)\right) \quad \text { for every Borel set } A . \tag{1.1}
\end{equation*}
$$

It is well known, and easy to verify, that the before mentioned sets $A_{r}$ are also the attractors of the IFS of contracting similitudes $\left\{g_{r, 0}, g_{r, 1}\right\}$ defined on $[0,1]$, where $g_{r, i}=r x+i(1-r)$. These are the simplest examples of regular or dynamically defined Cantor set, where in general, the derivatives of the functions of the IFS are assumed be at least $\epsilon$-Hölder continuous for some $0<\epsilon<1$ (see Section 2). We write $\mathcal{C}^{1+\epsilon}$-regular to emphasize that the functions of the system are of class $\mathcal{C}^{1+\epsilon}$. An important feature of regular Cantor sets is that their Hausdorff and Box dimensions coincide; in addition, their Hausdorff and packing measures on this dimensional value are finite and positive. This motivates us to prove in Section 3 that
 $C_{p}$ as attractor; see Theorem 4.

In view of the above theorem, $C_{p}$ has a $\mathcal{C}^{1+1 / p}$-differentiable structure. By a result of Sullivan [Sul88], this structure can be classified by its scaling function (defined in Section 4). More precisely, two regular IFS $\left\{f_{0}, f_{1}\right\}$ and $\left\{\tilde{f}_{0}, \tilde{f}_{1}\right\}$ are equivalent if they are smoothly conjugate, that is, if there exists a smooth homeomorphism $h$, termed conjugacy, such that

$$
h \circ f_{i}=\tilde{f}_{i} \circ h, \quad i=0,1 ;
$$

here by smooth we mean that $h$ and its inverse are at least $\mathcal{C}^{1}$. Then, the result in [Sul88] says that the scaling function is a complete invariant: two $\mathcal{C}^{1+\epsilon}$-regular systems are equivalent if and only if their scaling functions coincide. Moreover, there is a conjugacy which is $\mathcal{C}^{1+\epsilon}$; for a proof of this see [PT96] and [BF97]. It turns out that the scaling functions of the regular Cantor sets $C_{p}$ and $A_{2^{-p}}$ coincide, as will be shown in Section 4. Therefore, these systems are $\mathcal{C}^{1+1 / p}$-conjugate; see Theorem 13. Moreover, since the attractors of conjugate systems satisfy $\widetilde{C}=h(C)$, then the sets $C_{p}$ and $A_{2-p}$ are $\mathcal{C}^{1+1 / p_{-}}$-diffeomorphic images of each other.

In order to introduce the last results of the paper, let

$$
\mu_{r}(A)=\frac{1}{2} \mu_{r}\left(g_{r, 0}^{-1}(A)\right)+\frac{1}{2} \mu_{r}\left(g_{r, 1}^{-1}(A)\right) \quad \text { for every Borel set } A .
$$

In this particular case, $\mu_{r}=\left.\mathcal{H}^{d_{r}}\right|_{A_{r}}([\operatorname{Hut} 81])$, where $d_{r}=\operatorname{dim} A_{r}$ and $\left.\mathcal{H}^{d_{r}}\right|_{A_{r}}$ is the restriction of the Hausdorff measure to $A_{r}$. Now let us look at the convolution measure $\mu_{r} * \mu_{r}$. Since all the similitudes have the same ratio of contraction, it is easily verified that it satisfies an identity as the one in (1.1), with IFS $\{r x, r x+1-r, r x+2(1-r)\}$ and weights $(1 / 4,1 / 2,1 / 4)$. Thus it is a measure of pure type, i.e., either absolutely continuous or purely singular with respect to $\mathcal{L}$, the Lebesgue measure on $\mathbb{R}$ (see [PSS00], Proposition 3.1). This motivated us to ask whether the measure $\left.\left.\mathcal{H}^{1 / p}\right|_{C_{p}} * \mathcal{H}^{1 / p^{\prime}}\right|_{C_{p^{\prime}}}$ is of pure type. Henceforth, absolutely continuous or singular will be meant with respect to $\mathcal{L}$.

Let us denote by $\mathcal{H}_{p}$ the measure $\left.\mathcal{H}^{1 / p}\right|_{C_{p}}$. The support of $\mathcal{H}_{p} * \mathcal{H}_{p^{\prime}}$ is contained in the sumset $C_{p}+C_{p^{\prime}}$, thus in this setting it is also important to determine the size of this set.

Due to a classical result of Newhouse, the thickness of a Cantor set is a useful tool to determine whether the sum of two of these sets has nonempty interior. Through an estimate of thickness, we provide sufficient conditions on the parameters $p$ and $p^{\prime}$ so that $C_{p}+C_{p^{\prime}}$ has nonempty interior. We show that in order to have analogous conditions to the classical case, it is necessary to consider a local version of thickness.

Finally, we concentrate on the convolution of measures and the dimensional behaviour of sumsets, but from a measure theoretical point of view. For any pair of sets $E, F \subset \mathbb{R}$, with $\operatorname{dim} F=\operatorname{dim}_{B} F$, it is well known that $\operatorname{dim}(E+F) \leq \operatorname{dim}(E \times F) \leq \operatorname{dim} E+\operatorname{dim} F$ (see Mattila [Mat95]). Hence it is always true that

$$
\operatorname{dim}\left(C_{p}+C_{p^{\prime}}\right) \leq \min \left(\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}, 1\right) .
$$

Therefore $\mathcal{H}_{p} * \mathcal{H}_{p^{\prime}}$ is trivially singular if $\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}<1$ because $\mathcal{L}\left(C_{p}+C_{p^{\prime}}\right)=0$. We prove that the convolution is absolutely continuous when $\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}>1$, with the possible exception of a small set in the parameter. More precisely, let $p^{\prime}$ be fixed and $\bar{p}$ be such that $\operatorname{dim} C_{p^{\prime}}+\operatorname{dim} C_{\bar{p}}=1$. Also, let us denote with $\nu \in L^{2}\left(\nu \notin L^{2}\right)$ the fact that the measure $\nu$ has (does not have) a density in $L^{2}(\mathbb{R})$. Then, for any $\varepsilon>0$ there is a $\delta=\delta(\varepsilon)>0$ (which decreases to 0 with $\varepsilon$ ) such that

$$
\begin{equation*}
\operatorname{dim}\left\{p \in(1, \bar{p}-\varepsilon): \mathcal{H}_{p} * \mathcal{H}_{p^{\prime}} \notin L^{2}\right\} \leq 1-\delta \tag{1.2}
\end{equation*}
$$

In particular, $\mathcal{H}_{p} * \mathcal{H}_{p^{\prime}} \in L^{2}$ for $\mathcal{L}$-a.e. $p$ such that $\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}>1$.
Observe that (1.2) implies that

$$
\begin{equation*}
\operatorname{dim}\left\{p \in(1, \bar{p}-\varepsilon): \mathcal{L}\left(C_{p}+C_{p^{\prime}}\right)=0\right\}<1-\delta . \tag{1.3}
\end{equation*}
$$

Moreover, we show that

$$
\begin{equation*}
\operatorname{dim}\left\{p \in(\bar{p}+\varepsilon, \infty): \operatorname{dim}\left(C_{p}+C_{p^{\prime}}\right)<\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}\right\}<1-\delta . \tag{1.4}
\end{equation*}
$$

In particular, the formula

$$
\operatorname{dim}\left(C_{p}+C_{p^{\prime}}\right)=\min \left(\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}, 1\right)
$$

holds for almost every $p$.
We can replace $C_{p^{\prime}}$ and $\mathcal{H}_{p^{\prime}}$ above by any compact $K \subset \mathbb{R}$ and a suitable measure; besides, more general families of Cantor sets can be used instead of $\left\{C_{p}\right\}_{p}$; see Theorems 17 and 19.

These last results are a consequence of the Peres-Schlag projection theorem; see [PS00]. In that paper, the dimensional bounds of exceptions (1.3) and (1.4) are obtained for families of homogeneous Cantor sets, being each of these sets by definition an attractor of an IFS of similitudes, all of them with the same ratio of contraction.
1.3. Background and related works. In connection with dynamically defined Cantor sets, Bamón et al in [BMPV97] considered central Cantor sets, which by definition satisfies that on each step the removed gaps have the same length. In that paper those central Cantor sets that are $\mathcal{C}^{k+\epsilon}$ or $\mathcal{C}^{\infty}$-regular are characterized in terms of the decay of the sequence. Moreover, it is provided a classification of these sets up to local and global diffeomorphisms.

The structure and dimension of sums of Cantor sets are relevant in different areas such as diophantine approximations in number theory and homoclinic tangencies in smooth dynamics. In this context, Palis (see [PT93]) asked whether the sum of two regular Cantor sets has zero Lebesgue measure or contains an open interval. There are particular cases where this is not true, as it was shown by Sannami [San92], but Moreira and Yoccoz [MY01] proved that generically (in the $\mathcal{C}^{1+\epsilon}$ topology on regular Cantor sets) the conjecture is true. Nevertheless,
the question for the self-similar case is still open, although for the special case of $A_{r}+A_{r}$ it is true, see Cabrelli et al [CHM97].

Related to the size of sumsets, if $C_{1}$ and $C_{2}$ are strictly nonlinear $\mathcal{C}^{2}$-regular Cantor sets, the formula $\operatorname{dim}\left(C_{1}+C_{2}\right)=\min \left(\operatorname{dim} C_{1}+\operatorname{dim} C_{2}, 1\right)$ is true under some explicit conditions on the IFS; see Moreira [M98]. For the linear case, given a compact set $K \subset \mathbb{R}$, the equality

$$
\begin{equation*}
\operatorname{dim}\left(K+A_{r}\right)=\min \left(\operatorname{dim} K+\operatorname{dim} A_{r}, 1\right) \text { for } \mathcal{L} \text {-a.e. } r \tag{1.5}
\end{equation*}
$$

was established by Peres and Solomyak [PS98]. It was improved in [PS00] as we mentioned above. Moreover, recently Peres and Shmerkin [PS09] found exactly the exceptional set when $K=A_{s}$ : equality holds if and only if $\log r / \log s$ is irrational. This condition also appears in the study of the topological structure of the sumset when $\operatorname{dim} A_{s}+\operatorname{dim} A_{r}>1$; see Mendes and Oliveira [MO94] and Cabrelli et al [CHM02].

By the Riemann-Lebesgue lemma, a necessary condition for absolute continuity of a measure is that its Fourier transform vanishes at infinity. Now, it is well known that the Fourier transform of $\mu_{r}$, denoted by $\hat{\mu}_{r}$, does not tend to 0 at infinity if and only if $1 / r$ is a Pisot number different from 2 (Pisot numbers are a special class of algebraic integers); see [Sal63]. By a general property of convolutions, $\widehat{\mu_{r} * \mu_{r}}=\hat{\mu}_{r} \cdot \hat{\mu}_{r}$, whence $\mu_{r} * \mu_{r}$ is singular if $r$ is the reciprocal of a Pisot number; however it may happen that $\mathcal{L}\left(A_{r}+A_{r}\right)>0$. For example, this is the case when $r=1 / 3$. Lau et al ([FLN00], [HL01]) studied the multifractal structure of the $m$-th convolution of the measure $\mu_{1 / 3}$, which is singular by the above argument. Nazarov et al [NPS09] determined that the correlation dimension of $\mu_{r} * \mu_{s}$ is $\min \left(d_{r}+d_{s}, 1\right)$ whenever $\log r / \log s$ is irrational.

Pablo Shmerkin informed us that in a joint work with Michael Hochman [HS09] they generalize the work on sums of Cantor sets [PS09] and their methods implies that the dimension of the convolution $\mathcal{H}_{p} * \mathcal{H}_{p^{\prime}}$ is $\min \left(1, \operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}\right)$ whenever $p / p^{\prime}$ is irrational. This in turns implies that for these parameters formula (1.2) holds. However, when the sum of the dimensions is greater than 1 they do not obtain results on the absolute continuity of the convolution.

## Some open questions:

1) We do not know if the convolution of two invariant measures associated to regular Cantor sets is of pure type. Even we do not know this for $v_{p} * v_{p^{\prime}}$, although here we show that this is almost every where true.
2) For which values $p>1$ does the Fourier transform of $v_{p}$ vanish at infinity?. If $h_{p}$ is the diffeomorphism between $A_{2^{-p}}$ and $C_{p}$ (which exists by Theorem 13) then the relation

$$
v_{p}=\mu_{2^{-p}} \circ h_{p}^{-1}
$$

holds by uniqueness of the invariant measure. Although we know this identity, the nonlinearity of the diffeomorphism $h_{p}$ does not allows us to transfer the information from $\mu_{2^{-p}}$ to $v_{p}$ in order to estimate the decay of its Fourier transform (recall that $\hat{\mu}_{r} \rightarrow 0$ iff $r$ is not the reciprocal of a Pisot number).

## 2. Basic definitions and notation

In this section we provide the basic definitions and notation that we will use later.
The symbolic space. Given $n \geq 1$, let $\Omega_{n}$ be the set of binary strings of length $n$, that is

$$
\Omega_{n}=\left\{\omega_{1} \ldots \omega_{n}: \omega_{i}=0,1 \text { with } 1 \leq i \leq n\right\} .
$$

Set $\Omega_{0}=\{e\}$ with $e$ the empty string and let $\Omega^{*}=\bigcup_{n \geq 0} \Omega_{n}$. Define $\Omega=\left\{\omega_{1} \omega_{2} \ldots: \omega_{i}=\right.$ $0,1$ with $i \in \mathbb{N}\}$, the set of binary infinite strings. The length of $\omega \in \Omega^{*} \bigcup \Omega$ is denoted by $|\omega|$. Elements in $\Omega$ have infinite length. Given $\omega \in \Omega^{*} \bigcup \Omega$ with $|\omega| \geq k$, its $k$-truncation is $\left.\omega\right|_{k}=\omega_{1} \ldots \omega_{k}$. The infinite string with all entries 0 is denoted by $\overline{0}$; analogously, we define $\overline{1}$. Moreover, if $\omega \in \Omega^{*}$ and $\tau \in \Omega^{*} \bigcup \Omega$ then $\omega \tau$ denotes the string obtained by juxtaposing the elements of $\omega$ and $\tau$. Furthermore, for $\omega \in \Omega_{n}$ denote with $\ell(\omega)$ the binary representation

$$
\ell(\omega)=\sum_{j=1}^{n} \omega_{j} 2^{n-j}
$$

Given $\beta>1$, we define a metric on $\Omega$ by

$$
d_{\beta}(\omega, \tau)=\left\{\begin{array}{cl}
\beta^{-|\omega \wedge \tau|} & \text { if } \omega \neq \tau \\
0 & \text { if } \omega=\tau
\end{array}\right.
$$

where $|\omega \wedge \tau|=\min \left\{k: \omega_{k} \neq \tau_{k}\right\}$. The space $\left(\Omega, d_{\beta}\right)$ is a compact, perfect and totally disconnected metric space.

Cantor set associated to a sequence. Let $a=\left\{a_{j}\right\}$ be a positive and summable sequence and let $I_{a}$ be the closed interval $\left[0, \sum_{j} a_{j}\right]$. We define the zero Lebesgue measure Cantor set $C_{a}$ associated to the sequence $a$ as follows. In the first step, we remove from $I_{a}$ an open interval $L_{1}$ of length $a_{1}$, termed gap, resulting in two closed intervals $I_{0}^{1}$ and $I_{1}^{1}$. Having constructed the $k$-th step, we obtain the $2^{k}$ closed intervals $I_{\omega}^{k}, \omega \in \Omega_{k}$, contained in $I_{a}$. The next step consists in removing from $I_{\omega}^{k}$ the gap $L_{2^{k}+\ell(\omega)}$ of length $a_{2^{k}+\ell(\omega)}$, obtaining the closed intervals $I_{\omega 0}^{k+1}$ and $I_{\omega 1}^{k+1}$. Then we define

$$
C_{a}:=\bigcap_{k=1}^{\infty} \bigcup_{\omega \in \Omega_{k}} I_{\omega}^{k}
$$

The intervals $I_{\omega}^{k}$ are the basic intervals of $C_{a}$. It is convenient to use also the decimal notation for this intervals, so we define $I_{l}^{k}=I_{\omega}^{k}$, where $l=\ell(\omega)$.

Remark. In the above construction there is a unique way of removing the open intervals at each step. Also notice that not necessarily the lengths of the closed intervals of the same step coincide. In fact, for $\omega \in \Omega_{k}$ we have by construction that

$$
\begin{equation*}
I_{\omega}^{k}=I_{\omega 0}^{k+1} \bigcup L_{2^{k}+\ell(\omega)} \bigcup I_{\omega 1}^{k+1} \tag{2.1}
\end{equation*}
$$

then, applying this identity recursively to each closed interval of the right hand side, the length of the intervals is given by

$$
\begin{equation*}
\left|I_{\omega}^{k}\right|=\sum_{n \geq k} \sum_{\lambda \in \Omega_{n-k}} a_{2^{n}+\ell(\omega \lambda)} \tag{2.2}
\end{equation*}
$$

or

$$
\begin{equation*}
\left|I_{l}^{k}\right|=\sum_{h \geq 0} \sum_{j=l 2^{h}}^{(l+1) 2^{h}-1} a_{2^{k+h}+j} \tag{2.3}
\end{equation*}
$$

using the other notation.
Recall that $C_{p}$ is the Cantor set associated to $\left\{1 / n^{p}\right\}_{n}$. In Section 5 we will work with the more general set $C_{p, q}$, that is the one associated to $\left\{(\log n)^{q} / n^{p}\right\}_{n}$ (the term corresponding to $n=1$ is defined as 1 ). Here $p>1$ and $q \in \mathbb{R}$. It is known that $\operatorname{dim} C_{p, q}=1 / p$, but $\mathcal{H}^{1 / p}\left(C_{p, q}\right)=0$ if $q<0$ and $\mathcal{H}^{1 / p}\left(C_{p, q}\right)=+\infty$ if $q>0$; see [GMS07].

The next lemma states the bounds for the basic intervals of $C_{p, q}$ that will be used throughout the paper.
Lemma 1. If $I_{l}^{k}$ is a $k$-step interval of $C_{p}$ then

$$
\begin{equation*}
\left(\frac{1}{2^{k}+l+1}\right)^{p} \frac{2^{p}}{2^{p}-2} \leq\left|I_{l}^{k}\right| \leq \frac{2^{p}}{2^{p}-2}\left(\frac{1}{2^{k}+l}\right)^{p} . \tag{2.4}
\end{equation*}
$$

Moreover, if $I_{l}^{p, q}$ is a $k$-step interval of $C_{p, q}$ then

$$
\begin{equation*}
\frac{k^{q}}{2^{k p}} c_{p, q} \leq\left|I_{l}^{p, q}\right| \leq c_{p, q}^{\prime} \frac{k^{q}+1}{2^{k p}}, \tag{2.5}
\end{equation*}
$$

where $c_{p, q}$ and $c_{p, q}^{\prime}$ depend continuously on $p$ and $q$.
Proof. Estimate (2.4) is given in [CMPS05], Lemma 3.2. The lower bound in (2.5) holds since $I_{l}^{p, q} \supset L_{2^{k}+l}$ and $\left|L_{2^{k}+l}\right|>\left|L_{2^{k+1}}\right|$. The remaining bound is obtained using (2.3):

$$
\begin{aligned}
\left|I_{l}^{k}\right| & =\sum_{h \geq 0} \sum_{j=l 2^{h}}^{(l+1) 2^{h}-1} \frac{\left(\log \left(2^{k+h}+j\right)\right)^{q}}{\left(2^{k+h}+j\right)^{p}} \\
& \leq \sum_{h \geq 0} 2^{h} \frac{\left(\log \left(2^{h}\left(2^{k}+l+1\right)\right)\right)^{q}}{\left(2^{h}\left(2^{k}+l\right)\right)^{p}} \\
& \leq c_{p, q}^{\prime} \frac{k^{q}+1}{2^{k p}} .
\end{aligned}
$$

Given $\omega \in \Omega^{*} \cup \Omega$, with $|\omega| \geq k$, we define

$$
I_{\omega}^{k}=I_{\omega \mid k}^{k} .
$$

Observe that for $\omega \in \Omega$, the family $\left\{I_{\omega}^{k}\right\}_{k}$ is a nested sequence of closed intervals whose intersection is a single point. Thus we define the projection map $\pi: \Omega \rightarrow C$ by

$$
\begin{equation*}
\pi(\omega)=\bigcap_{k \geq 1} I_{\omega}^{k} \tag{2.6}
\end{equation*}
$$

Endowed with the lexicographical order on $\Omega$, this map is an order preserving homeomorphism and provides a natural way to code the Cantor set. For notational convenience we will identify the point $\omega \in \Omega$ with $\bigcap_{k \geq 1} I_{\omega}^{k} \in C$.

By the endpoints of a Cantor set $C_{a}$ we mean the set of endpoints of all the intervals $I_{\omega}^{k}$ with $\omega \in \Omega_{k}, k \geq 1$. The next proposition says that endpoints correspond to points of the form $\omega \bar{u}$, where $\omega \in \Omega^{*}$ and $u=0,1$.
Proposition 2. For $\omega \in \Omega_{k}$ we have that

$$
I_{\omega}^{k}=[\pi(\omega \overline{0}), \pi(\omega \overline{1})] \quad \text { and } \quad L_{2^{k}+\ell(\omega)}=(\pi(\omega 0 \overline{1}), \pi(\omega 1 \overline{0})) .
$$

Proof. The result follows from the definition of $\pi$ and its order preserving property. We omit the details.

Regular Cantor sets. For simplicity let $I=[0,1]$. Consider an IFS of diffeomorphisms $\left\{f_{0}, f_{1}\right\}$ defined on $I$ such that

$$
0=f_{0}(0)<f_{0}(1)<f_{1}(0)<f_{1}(1)=1
$$

and the derivatives are $\eta$-Hölder continuous, i.e.,

$$
\left|f_{i}^{\prime}(x)-f_{i}^{\prime}(y)\right| \leq c|x-y|^{\eta} \quad \text { for all } x, y \in I
$$

Such an IFS is called $\mathcal{C}^{1+\eta}$-regular.
The first condition implies that the attractor is already a Cantor set of zero Lebesgue measure. If we would only require differentiability to the system, the Hausdorff and box dimensions of the attractor coincide, but the addition of the Hölder condition assures that, in the corresponding dimensional parameter, the Hausdorff and packing measures are positive and finite.

Given $\omega \in \Omega_{k}$ we set $f_{\omega}=f_{\omega_{1}} \circ \cdots \circ f_{\omega_{k}}$. It is easily seen that the attractor of a regular system is given by

$$
C=\bigcap_{k \geq 0} \bigcup_{\omega \in \Omega_{k}} f_{\omega}(I) .
$$

Finally, we note that in view of the next proposition, the convolution measures $v_{p} * v_{q}$ and $\mathcal{H}_{p} * \mathcal{H}_{p}$ are equivalent, and thus in Section 5 we will work with the former.

Proposition 3. $v_{p}$ is equivalent to $\mathcal{H}_{p}$.
Proof. Recall that $h_{p}\left(A_{2^{-p}}\right)=C_{p}$. Given $B \subset[0,1]$ we have that

$$
\begin{aligned}
v_{p}(B) & =\mu_{2^{-p}}\left(h_{p}^{-1}(B)\right) \\
& =\mathcal{H}^{1 / p}\left(h_{p}^{-1}(B) \cap A_{2^{-p}}\right)=\mathcal{H}^{1 / p}\left(h_{p}^{-1}\left(B \cap C_{p}\right)\right) .
\end{aligned}
$$

Since $h_{p}$ is a bi-Lipschitz function, there is a constant $c>0$ such that

$$
c^{-1} \mathcal{H}^{1 / p}\left(B \cap C_{p}\right) \leq \mathcal{H}^{1 / p}\left(h_{p}^{-1}\left(B \cap C_{p}\right)\right) \leq c \mathcal{H}^{1 / p}\left(B \cap C_{p}\right),
$$

whence the measures are equivalent.

## 3. $C_{p}$ is a regular Cantor set

In this section we show that $C_{p}$ is a regular Cantor set. More precisely we prove the following theorem.

Theorem 4. The set $C_{p}$ is a $\mathcal{C}^{1+1 / p}$-regular Cantor set. Moreover this is the highest degree of smoothness that can be attained by any other regular system that has this set as attractor.

A sufficient condition for an $\operatorname{IFS}\left\{f_{0}, f_{1}\right\}$ to have $C_{p}$ as its attractor is that

$$
\begin{equation*}
f_{\omega}(I)=I_{\ell(\omega)}^{k}, \quad \text { for all } \omega \in \Omega_{k} \text { and } k \geq 1 \tag{3.1}
\end{equation*}
$$

Thus, in order to prove our theorem it is enough to find functions that satisfy the above properties. The existence of such functions is not evident, moreover if we want them to be smooth. The proof of our theorem is motivated by the following necessary condition for the derivatives of the functions of an IFS at the points of its attractor.

Proposition 5. Assume that $C$ is the attractor of an $\operatorname{IFS}\left\{f_{0}, f_{1}\right\}$ with continuous positive derivatives. Given $x \in C$, let $\omega \in \Omega$ be such that $x=\pi(\omega)$. Then the derivative at $x$ is given by the limit

$$
\begin{equation*}
f_{i}^{\prime}(x)=\lim _{n \rightarrow \infty} \frac{\left|f_{i \omega}(I)\right|}{\left|f_{\omega}(I)\right|}, \quad i=0,1 \tag{3.2}
\end{equation*}
$$

Proof. By the mean value theorem we have that

$$
\begin{equation*}
\left|f_{\left.i \omega\right|_{n}}(I)\right|=\left|f_{i}\left(f_{\left.\omega\right|_{n}}(I)\right)\right|=f_{i}^{\prime}\left(\xi_{n}\right)\left|f_{\left.\omega\right|_{n}}(I)\right|, \tag{3.3}
\end{equation*}
$$

where $\xi_{n} \in f_{\left.\omega\right|_{n}}(I)$. As $n$ goes to infinite, $\xi_{n}$ tends to the unique point $x \in C$ which is in the intersection $\bigcap_{n \geq 1} f_{\left.\omega\right|_{n}}(I)$. Thus (3.2) follows from the positiveness and continuity of $f^{\prime}$.

Therefore this proposition provides us with the starting point. The proof of Theorem 4 has essentially two parts. First we prove that for each endpoint $\omega \in \Omega$, the sequence of quotients

$$
\begin{equation*}
\left\{\left|I_{\ell\left(\left.i \omega\right|_{n}\right)}^{n+1}\right| /\left|I_{\ell\left(\left.\omega\right|_{n}\right)}^{n}\right|\right\}_{n} \tag{3.4}
\end{equation*}
$$

converges and we find an expression for the limit. Thus by (3.2) these limits should be the values, at the endpoints of our Cantor set, of the derivatives of the functions of an IFS that satisfies (3.1). Then, with these values, in the second part we are able to extend the derivatives to the whole interval $I$ so that (3.1) holds and thus the system has $C_{p}$ as its attractor.

Notice that if the derivatives are positive then $f_{i}$ is order preserving, so $f_{0}(0)=0$ and $f_{1}(|I|)=|I|$. From this, once we have constructed the derivatives $F_{0}$ and $F_{1}$ we define

$$
\begin{equation*}
f_{0}(x)=\int_{0}^{x} F_{0} \quad \text { and } \quad f_{1}(x)=\int_{0}^{x} F_{1}+c \tag{3.5}
\end{equation*}
$$

with $c=\left|I_{0}^{1}\right|+1$, since 1 is the length of the first gap.
3.1. Definition of the derivatives on $\boldsymbol{C}_{\boldsymbol{p}}$ and properties. Recall that endpoints of $C_{\boldsymbol{p}}$ correspond to strings of the form $\omega \bar{u}$, with $u=0$ or 1 and $\omega \in \Omega_{k}, k \geq 1$. We have the following result.
Proposition 6. At each endpoint $\omega \bar{u}$ of $C_{p}$ the limit of $\left\{\left|I_{\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)}^{n+1}\right| /\left|I_{\ell\left(\left.(\omega \bar{u})\right|_{n}\right)}^{n}\right|\right\}_{n}$ exists. It is given by the formula

$$
\begin{equation*}
G_{i}(\omega \bar{u})=\left(\frac{2^{k}+\ell(\omega)+u}{2^{k+1}+i 2^{k}+\ell(\omega)+u}\right)^{p}, \quad \omega \in \Omega_{k}, u=0,1 \tag{3.6}
\end{equation*}
$$

Proof. Let $\omega \in \Omega_{k}$ with $k \geq 1$. It follows from (2.4) that

$$
\left(\frac{2^{n}+\ell\left(\left.(\omega \bar{u})\right|_{n}\right)}{2^{n+1}+\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)+1}\right)^{p} \leq \frac{\left|I_{\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)}^{n+1}\right|}{\left|I_{\ell\left(\left.(\omega \bar{u})\right|_{n}\right)}^{n}\right|} \leq\left(\frac{2^{n}+\ell\left(\left.(\omega \bar{u})\right|_{n}\right)+1}{2^{n+1}+\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)}\right)^{p}
$$

From equalities

$$
\ell\left(\left.(\omega \bar{u})\right|_{n}\right)=\sum_{j=1}^{k} \omega_{j} 2^{n-j}+u\left(2^{n-k}-1\right)=2^{n-k}\left(\ell(\omega)+u\left(1-1 / 2^{n-k}\right)\right)
$$

and

$$
\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)=i 2^{n}+\ell\left(\left.(\omega \bar{u})\right|_{n}\right),
$$

we get

$$
\frac{\left|I_{\ell\left(\left.i(\omega \bar{u})\right|_{n}\right)}^{n+1}\right|}{\left|I_{\ell\left(\left.(\omega \bar{u})\right|_{n}\right)}^{n}\right|} \leq\left(\frac{2^{k}+\ell(\omega)+u\left(1-1 / 2^{n-k}\right)+1 / 2^{n-k}}{2^{k+1}+i 2^{k}+\ell(\omega)+u\left(1-1 / 2^{n-k}\right)}\right)^{p}
$$

with a similar lower bound. Since $\ell(\omega)$ is independent of $n$, the limit of the sequence (3.4) exists and is given by (3.6).

Remark. In fact, the limit in the above proposition exists not only at the endpoints but in all $C_{p}$. For our purposes however it is enough to know the values at the endpoints.

Let us denote with $E_{p}$ the set of endpoints of $C_{p}$. The functions of the previous proposition have the following properties.

Lemma 7. Let $G_{i}, i=0,1$ be defined on $E_{p}$ by formula (3.6). Then
(a) Each function $G_{i}$ takes the same value at the endpoints of a single gap; that is, at the endpoints of $L_{2^{k}+\ell(\omega)}$ we have that $G_{i}(\omega 0 \overline{1})=G_{i}(\omega 1 \overline{0}), \omega \in \Omega_{k}, k \geq 0, i=0,1$.
(b) Both functions $G_{0}$ and $G_{1}$ are increasing.
(c) For every $\omega \in \Omega_{k}, u=0,1$

$$
\left(\frac{1}{2}\right)^{p} \leq G_{0}(\omega \bar{u}) \leq\left(\frac{2}{3}\right)^{p} \quad \text { and } \quad\left(\frac{1}{3}\right)^{p} \leq G_{1}(\omega \bar{u}) \leq\left(\frac{1}{2}\right)^{p}
$$

Proof. (a) Since $\ell(\omega 1)=\ell(\omega 0)+1$, the statement is a consequence of the definition of $G_{i}$.
(b) By the previous item and the continuity of $G_{i}$ it is enough to show that this function is increasing in the left endpoints. Let $\omega \in \Omega_{k-1}, v \in \Omega_{l-1}$ and suppose that $\omega 1 \overline{0} \prec v 1 \overline{0}$. By (3.6) we must see that

$$
\left(\frac{2^{k}+\ell(\omega 1)}{2^{k+1}+i 2^{k}+\ell(\omega 1)}\right)^{p}<\left(\frac{2^{l}+\ell(v 1)}{2^{l+1}+i 2^{l}+\ell(v 1)}\right)^{p}
$$

This is equivalent to

$$
2^{l} \ell(\omega 1)<2^{k} \ell(v 1)
$$

Let $h \leq \min (k-1, l-1)$ be the first integer such that $\omega_{h} \neq v_{h}$, so that $\omega_{j}=v_{j}$ if $j<h$, $\omega_{h}=0$ and $v_{h}=1$. Define $\omega_{k}=v_{l}=1$. Then we have that

$$
\begin{aligned}
2^{l} \ell(\omega 1) & =2^{l} \sum_{j=1}^{h-1} \omega_{j} 2^{k-j}+2^{l} \sum_{j=h+1}^{k} \omega_{j} 2^{k-j} \\
& \leq \sum_{j=1}^{h-1} \omega_{j} 2^{k+l-j}+2^{l}\left(2^{k-h}-1\right) \\
& <\sum_{j=1}^{h-1} v_{j} 2^{k+l-j}+2^{k+l-h} \\
& \leq 2^{k} \sum_{j=1}^{l-1} v_{j} 2^{l-j}=2^{k} \ell(v 1)
\end{aligned}
$$

$(c)$ is consequence of $(b)$ and the values of the functions at the endpoints of $I$.
Note that item $(c)$ emphasizes that the derivatives are strictly less than 1 in $C_{p}$.
Below we establish the Hölder regularity of $G_{i}$ on $E_{p}$.
Proposition 8. Let $G_{i}$ be as above. Then $G_{i} \in \mathscr{C}^{1 / p}\left(E_{p}\right)$ but $G_{i} \notin \mathscr{C}^{\eta}\left(E_{p}\right)$ for any $\eta>1 / p$.
Proof. Firstly assume that $x$ and $y$ are endpoints of the same interval of the $m$-step. By Proposition 2, there exists $\omega \in \Omega_{m}$ such that $x=\omega \overline{0}$ and $y=\omega \overline{1}$. Applying formula (3.6), we have $G_{i}(\omega \overline{0})=\left(\frac{a}{b}\right)^{p}$ and $G_{i}(\omega \overline{1})=\left(\frac{a+1}{b+1}\right)^{p}$, with $a=2^{k}+\ell(\omega)$ and $b=2^{k+1}+i 2^{k}+\ell(\omega)$.

By the mean value theorem (with $a<\xi<b$ ) we have

$$
G_{i}(\omega \overline{1})-G_{i}(\omega \overline{0})=\frac{p(a b+\xi)^{p-1}(b-a)}{(b(b+1))^{p}}=\frac{p(a+\xi / b)^{p-1} 2^{k}(1+i)}{b(b+1)^{p}}
$$

since $b-a=2^{k}(1+i)$. Since

$$
1 / 5 \leq \frac{a+\xi / b}{b+1}, \frac{2^{k}(1+i)}{b} \leq 1
$$

by inequalities (2.4) there are positive and finite quantities $c_{1}$ and $c_{2}$ depending only on $p$ such that

$$
\begin{equation*}
c_{1}\left|I_{\ell(\omega)}^{k}\right|^{1 / p} \leq G_{i}(\omega \overline{1})-G_{i}(\omega \overline{0}) \leq c_{2}\left|I_{\ell(\omega)}^{k}\right|^{1 / p} \tag{3.7}
\end{equation*}
$$

The last inequality says that $G_{i}$ is $1 / p$-Hölder continuous at the endpoints of each basic interval with constant independent of the interval. On the other hand, the first inequality shows that the exponent $1 / p$ cannot be improved. In fact, if there is an $\varepsilon>0$ such that $G_{i}(\omega \overline{1})-G_{i}(\omega \overline{0}) \leq c\left|I_{\ell(\omega)}^{k}\right|^{1 / p+\varepsilon}$ then $0<c_{1} c^{-1} \leq\left|I_{\ell(\omega)}^{k}\right|^{\varepsilon}$ for all $k$, which is impossible because $\left|I_{\ell(\omega)}^{k}\right| \rightarrow 0$ as $k$ increases. Therefore, the second claim is proved.

To complete the proof of the first claim we need the following result of [CMPS05] (Lemma $3.5)$ :

$$
\text { Let } J \text { be an open interval and let } k \in \mathbb{N} . \text { Then } \sum_{l: I_{l}^{k} \subset J}\left|I_{l}^{k}\right|^{1 / p} \leq 4|J|^{1 / p} \text {. }
$$

Let $x$ and $y$ be arbitrary endpoints and $\varepsilon>0$. We define $L_{\varepsilon}=(x-\varepsilon, y+\varepsilon)$. As a consequence of the construction note that $x$ and $y$ are endpoints of the $k$-step for some $k$, so let $x=x_{0}<\ldots<x_{N}=y$ be all the endpoints of the $k$-step between $x$ and $y$. By Lemma 7 (a) we have that $G_{i}\left(x_{n+1}\right)-G_{i}\left(x_{n}\right)=0$ if $\left(x_{n}, x_{n+1}\right)$ is a gap. Thus, using inequality (3.7) and the above lemma we obtain

$$
\begin{aligned}
\left|G_{i}(x)-G_{i}(y)\right| & =\left|\sum_{k=0}^{N-1} G_{i}\left(x_{k}\right)-G_{i}\left(x_{k+1}\right)\right| \leq \sum_{\omega: I_{\ell(\omega)}^{k} \subset L_{\varepsilon}}\left|G_{i}(\omega \overline{1})-G_{i}(\omega \overline{0})\right| \\
& \leq c_{2} \sum_{l: I_{l}^{k} \subset L_{\varepsilon}}\left|I_{l}^{k}\right|^{1 / p} \leq 4 c_{2}\left|L_{\varepsilon}\right|^{1 / p}
\end{aligned}
$$

and the result follows letting $\varepsilon \rightarrow 0$.
Remark. Once we have constructed an IFS with continuous derivatives that satisfies (3.1), it follows from the last proposition and denseness of $E_{p}$ that the derivatives are $1 / p$-Hölder continuous on all $C_{p}$.

The following lemma will be useful to prove the Hölder continuity of the extension.
Lemma 9. Let $f:(a, b) \rightarrow \mathbb{R}$ and let $a<c<b$ be such that $f$ restricted to the intervals $(a, c]$ and $[c, b)$ is $\alpha$-Hölder continuous with constants $C_{1}$ and $C_{2}$ respectively. Then $f$ is $\alpha$-Hölder continuous in $(a, b)$ with constant $C=2 \max \left\{C_{1}, C_{2}\right\}$.
Proof. Let $x \in(a, c)$ and $y \in(c, b)$. Then

$$
\begin{aligned}
|f(y)-f(x)| & \leq C_{2}(y-c)^{\alpha}+C_{1}(c-x)^{\alpha} \\
& \leq 2 \max \left\{C_{2}(y-c)^{\alpha}, C_{1}(c-x)^{\alpha}\right\} \\
& \leq C \max \left\{(y-c+c-x)^{\alpha},(c-x+y-c)^{\alpha}\right\}=C(y-x)^{\alpha}
\end{aligned}
$$

and the lemma is proved.
3.2. Construction of the derivatives. Here we define the derivatives $F_{i}$ extending the functions $G_{i}$ to the whole interval $I$ in such a way that $1 / p$-Hölder continuity be preserved and that equation (3.1) holds. Firstly we give an equivalent condition to this equation in terms of the lengths of gaps.

Lemma 10. Condition (3.1) is equivalent to $f_{0}(0)=0, f_{1}(|I|)=|I|$ and

$$
\begin{equation*}
\left|L_{2^{n+1}+\ell(i \omega)}\right|=\int_{L_{2^{n}+\ell(\omega)}} F_{i}, \quad \omega \in \Omega_{n}, \quad n \geq 0 \tag{3.8}
\end{equation*}
$$

Proof. Suppose that (3.8) holds. For $\omega \in \Omega_{n}$ let $\tilde{\omega}=\omega_{2} \ldots \omega_{n}$. Then by (2.2) we get

$$
\begin{align*}
\left|I_{\ell(\omega)}^{n}\right| & =\sum_{k \geq n} \sum_{\lambda \in \Omega_{k-n}}\left|L_{2^{k}+\ell(\omega \lambda)}\right| \\
& =\sum_{k \geq n} \sum_{\lambda \in \Omega_{k-n}} \int_{L_{2^{k-1}+\ell(\tilde{\omega} \lambda)}} F_{\omega_{1}}  \tag{3.9}\\
& =\int_{I_{\ell(\tilde{\omega})}^{n-1}} F_{\omega_{1}}=\left|f_{\omega_{1}}\left(I_{\ell(\tilde{\omega})}^{n-1}\right)\right| .
\end{align*}
$$

For $n=1$ this implies that $\left|f_{i}(I)\right|=\left|I_{i}^{1}\right|$, and since both intervals have a common endpoint it follows that they are the same. Inductively, if for $n \geq 1$ equality $f_{\omega}(I)=I_{\ell(\omega)}^{n}$ holds for all $\omega \in \Omega_{n}$, then

$$
\left|f_{\omega i}(I)\right|=\left|f_{\omega_{1}}\left(I_{\ell(\tilde{\omega} i)}^{n}\right)\right|=\left|I_{\ell(\omega i)}^{n+1}\right|,
$$

where we used (3.9) in the last equality. Hence each interval in the dynamical $n+1$-step has the same length as its corresponding interval associated to the sequence. Moreover, from $n=1$

$$
I_{\ell(\omega)}^{n}=f_{\omega}(I)=f_{\omega 0}(I) \bigcup f_{\omega}\left(L_{1}\right) \bigcup f_{\omega 1}(I)
$$

and recall by definition that

$$
\begin{equation*}
I_{\ell(\omega)}^{n}=I_{\ell(\omega 0)}^{n+1} \bigcup L_{2^{n}+\ell(\omega)} \bigcup I_{\ell(\omega 1)}^{n+1} ; \tag{3.10}
\end{equation*}
$$

then $f_{\omega i}(I)$ has a common endpoint with $I_{\ell(\omega i)}^{n+1}$ since $f_{\omega}$ is increasing. Therefore $f_{\omega}(I)=I_{\ell(\omega)}^{n}$ for all $\omega \in \Omega_{n}, n \geq 1$.

On the other hand, if (3.1) holds then $f_{0}(0)=0$ and $f_{1}(|I|)=|I|$; also by hypothesis

$$
I_{\ell(\omega)}^{n}=f_{\omega_{1}}\left(I_{\ell(\tilde{\omega})}^{n-1}(I)\right)=I_{\omega 0}^{n+1} \bigcup f_{\omega_{1}}\left(L_{2^{n-1}+\ell(\tilde{\omega})}\right) \bigcup I_{\omega 1}^{n+1}
$$

hence $f_{\omega_{1}}\left(L_{2^{n-1}+\ell(\tilde{\omega})}\right)=L_{2^{n}+\ell(\omega)}$ by (3.10), and equality (3.8) follows.
Obviously one can define on each gap a smooth function that satisfies the endpoint condition (3.6) and also (3.8), but we need to do this with a uniform bound of the Hölder constants on all gaps. Below we show that this can be realized if, for any gap in a sufficiently large step, the graph of $F_{i}$ on this gap coincides with the equal sides of an isosceles triangle as it is shown in Figure 3.1. This construction will be possible whenever the triangle is above the $x$-axis, since we want the derivatives to be positive.

Remark. The values of $G_{i}$ at the endpoints of each gap coincide (Lemma $7(a)$ ), but if we define $F_{i}$ on $L_{2^{n}+\ell(\omega)}$ as the constant value $G_{i}(\omega 1 \overline{0})$, then (3.8) does not hold because this function has too much area over this gap.

Let us denote with $h_{2^{n}+\ell(\omega)}^{i}$ the height of the triangle over the gap $L_{2^{n}+\ell(\omega)}$.
Lemma 11. There is an integer $n_{p}$ such that on each gap $L_{2^{n}+\ell(\omega)}$, with $\omega \in \Omega_{n}$ and $n \geq n_{p}$, it is possible to define a positive function $g_{\omega}$ through the isosceles triangle as in Figure 3.1 so that it satisfies (3.8). Moreover, for these gaps we have that $h_{2^{n}+\ell(\omega)}^{i} \leq \frac{p}{2^{n}}$. Furthermore, the $1 / p$-Hölder constants of these functions are uniformly bounded.
Proof. Let us define $l=\ell(\omega)$, so that $\ell(\omega 1)=2 l+1$ and $\ell(i \omega)=i 2^{n}+l$. Let $R$ be the area of the rectangle with base $L_{2^{n}+\ell(\omega)}$ and height $G_{i}(\omega 1 \overline{0})$ (the dotted rectangle in Figure 3.1). The area under the triangle decreases continuously as the vertex approaches the $x$-axis being equal to $1 / 2 R$ when they intersect. So, by condition (3.8), it is necessary to verify that $1 / 2 R<\left|L_{2^{n+1}+\ell(i \omega)}\right|$ for all $n$ big enough; that is

$$
\frac{1}{2}\left(\frac{1}{2^{n}+l}\right)^{p}\left(\frac{2^{n+1}+2 l+1}{2^{n+2}+i 2^{n+1}+2 l+1}\right)^{p}<\left(\frac{1}{2^{n+1}+i 2^{n}+l}\right)^{p}
$$

Writing $a=2^{n}+l$, the last inequality is equivalent to

$$
\left(\left(\frac{2 a+1}{2 a}\right)\left(\frac{a+2^{n}(1+i)}{a+2^{n}(1+i)+1 / 2}\right)\right)^{p}<2 .
$$

Each factor in the product tends to 1 as $n$ increases, thus the inequality holds for every $n \geq n_{p}$, where $n_{p}$ is an integer depending on $p$.

For $n \geq n_{p}$ we know the area of the triangle so we can estimate its height:

$$
\begin{aligned}
h_{2^{n}+l}^{i} & =2 \frac{R_{2^{n}+l}^{i}-\left|L_{2^{n+1}+i 2^{n}+l}^{i}\right|}{\left|L_{2^{n}+l}\right|} \\
& =2\left[\left(\frac{2^{n+1}+2 l+1}{2^{n+2}+i 2^{n+1}+2 l+1}\right)^{p}-\left(\frac{2^{n}+l}{2^{n+1}+i 2^{n}+l}\right)^{p}\right] .
\end{aligned}
$$

Applying the mean value theorem $(0<\xi<1 / 2)$ we obtain

$$
\begin{aligned}
h_{2^{n}+l}^{i} & =2\left[\left(\frac{a+1 / 2}{a+2^{n}(1+i)+1 / 2}\right)^{p}-\left(\frac{a}{a+2^{n}(1+i)}\right)^{p}\right] \\
& =2 p\left(\frac{a+\xi}{a+\xi+2^{n}(1+i)}\right)^{p-1} \frac{2^{n}(1+i)}{\left(a+2^{n}(1+i)+\xi\right)^{2}} \frac{1}{2} \\
& <\frac{p}{2^{n}} .
\end{aligned}
$$

For the last statement, let $\omega \in \Omega_{n}$ and $l=\ell(\omega)$. Let $s$ be the midpoint of $L_{2^{k}+l}$ and take $x$ and $y$ in this gap. The absolute value of the slope of the side of the triangle is $m_{2^{k}+l}^{i}=2 h_{2^{k}+l}^{i} /\left|L_{2^{k}+l}\right|$. First assume that $s \leq x, y$. Then

$$
\begin{aligned}
\left|g_{\omega}(x)-g_{\omega}(y)\right| & =m_{2^{k}+l}^{i}|x-y| \\
& \leq m_{2^{k}+l}^{i}\left|L_{2^{k}+l}\right|^{1-1 / p}|x-y|^{1 / p} \\
& \leq 4 p|x-y|^{1 / p} .
\end{aligned}
$$

Hence the Hölder constant is independent of $\omega$. The case $x, y \leq s$ is symmetric, and for $x<s<y$ the inequality follows using Lemma 9 given later.

Now we proceed to define the derivatives $F_{i}$, that will be the limit of a sequence of functions $\left\{F_{i}^{n}\right\}$. Each $F_{i}^{n}$ interpolates suitably the values of $G_{i}$ at the endpoints of the basic intervals of the $n$-step.

Figure 3.1
To begin with, on each gap $L_{k}$, with $1 \leq k \leq 2^{n_{p}}-1$ and $n_{p}$ as in Lemma 11, we define $F_{i}^{n_{p}}$ joining the values of $G_{i}$ at the endpoints of the gap so that it be $\mathcal{C}^{1}$, positive and its area under the gap be given by (3.8). On the remaining intervals, that is, on the closed intervals of the $n_{p}$-step, we interpolate linearly so that $F_{i}^{n_{p}}$ is a continuous function. For $n>n_{p}$ we define $F_{i}^{n}$ inductively: on the gap $L_{k}, 1 \leq k<2^{n-1}, F_{i}^{n}$ coincides with $F_{i}^{n-1}$; on the remaining gaps of the $n$-step, that is, on $L_{k^{\prime}}$, with $2^{n-1} \leq k^{\prime}<2^{n}$, we define the graph of $F_{i}^{n}$ as the sides of the isosceles triangle mentioned above; finally we complete the definition with linear interpolation.

The sequence $\left\{F_{i}^{k}\right\}_{k}$ has the following property.
Lemma 12. $\left\{F_{i}^{k}\right\}_{k}$ is a uniform Cauchy sequence.
Proof. It is enough to prove that $\left\|F_{i}^{k+1}-F_{i}^{k}\right\|_{\infty}=O\left(\frac{1}{2^{k}}\right)$ for every $k \geq n_{p}$. For this, notice that $F_{i}^{k}$ and $F_{i}^{k+1}$ coincide on the complementary gaps of the $k$-step, so we need to estimate their difference for points in the closed intervals of that step. Let $x \in I_{\ell(\omega)}^{k}=[\omega \overline{0}, \omega \overline{1}]$, with $\omega \in \Omega_{k}$. The functions are increasing in $C_{p}$ so (see Figure 3.2)

$$
G_{i}(\omega \overline{0}) \leq F_{i}^{k}(x) \leq G_{i}(\omega \overline{1})
$$

and

$$
G_{i}(\omega \overline{0})-h_{2^{k}+\ell(\omega)}^{i} \leq F_{i}^{k+1}(x) \leq G_{i}(\omega \overline{1}) .
$$

Then

$$
\begin{equation*}
\left|F_{i}^{k+1}(x)-F_{i}^{k}(x)\right| \leq G_{i}(\omega \overline{1})-G_{i}(\omega \overline{0})+h_{2^{k}+\ell(\omega)}^{i} . \tag{3.11}
\end{equation*}
$$

Therefore the result follows as a consequence of the estimate in Lemma 11, inequality (3.7) in the proof of Proposition 8 and since $\left|I_{\ell(\omega)}^{k}\right| \leq C 2^{-k p}$.

The previous lemma allows us to define $F_{i}$ as the (uniform) limit of $\left\{F_{i}^{k}\right\}_{k}$, which results a continuous function. Integrating we obtain the system $\left\{f_{p, 0}, f_{p, 1}\right\}$ that has $C_{p}$ as attractor.
Remark. Because of the freedom to extend the derivatives on each gap it is obvious that there is no uniqueness in the construction of the system.

Figure 3.2. $F_{i}^{k}$ in grey and $F_{i}^{k+1}$ in black.
End of proof of Theorem 4: It remains to show that $F_{i}$ is $1 / p$-Hölder continuous on $I$. Continuity and Proposition 8 implies this on $C_{p}$ (see the remark after that proposition). Also, by definition and Lemma 11, $F_{i}$ is $1 / p$-Hölder continuous on each gap with constant independent of the gap. Let $C$ be the maximum between this constant and the one given by Proposition 8. Take $x$ and $y$ in $I$ with $x<y$. If these points are in different gaps, let $e_{x}$ and $e_{y}$ denote the right and left endpoints of the respective gaps. Then

$$
\begin{aligned}
\left|F_{i}(x)-F_{i}(y)\right| & \leq\left|F_{i}(x)-F_{i}\left(e_{x}\right)\right|+\left|F_{i}\left(e_{x}\right)-F_{i}\left(e_{y}\right)\right|+\left|F_{i}\left(e_{y}\right)-F_{i}(y)\right| \\
& \leq C\left(\left|x-e_{x}\right|^{1 / p}+\left|e_{x}-e_{y}\right|^{1 / p}+\left|e_{y}-y\right|^{1 / p}\right) \\
& \leq 3 C|x-y|^{1 / p},
\end{aligned}
$$

which is what we need. The other possibilities for $x$ and $y$ in $I$ follows in the same way.

## 4. Conjugations

In this section we show how the sets $C_{p}$ and $A_{2^{-p}}$ are related. Since the attractors of conjugate (smooth) systems satisfy $\widetilde{C}=h(C)$, then they are diffeomorphic. In particular they have the same Hausdorff, packing and box dimensions, since these quantities are invariant under bilipschitz maps. Moreover, at their critical dimension, Hausdorff and packing measures are positive and finite. Nevertheless, these facts are not sufficient to ensure that the sets are smoothly conjugated.

Next we define the scaling function of a regular Cantor set, that is a complete invariant for this class of sets and is due to Sullivan ([Sul88]).

Let $\Delta$ be the unit simplex in $\mathbb{R}^{3}$, i.e.,

$$
\Delta=\{(a, b, c): a+b+c=1, a, b, c \geq 0\} .
$$

Given $\omega \in \Omega_{k}$ denote with $\omega^{\star}$ the reverse string $\omega_{k} \ldots \omega_{1}$. For a $\mathcal{C}^{1+\epsilon}$-regular Cantor $C$ and for each $\omega \in \Omega$, we define a function $R_{n}: \Omega \rightarrow \triangle$ by

$$
R_{n}(\omega)=\left(\left|I_{\left(\left.\omega\right|_{n}\right)^{\star 0}}\right|, \mid L_{\left(\left.\omega\right|_{n}\right)^{\star}\left|,\left|I_{\left(\left.\omega\right|_{n}\right)^{\star}}\right|\right) /\left|I_{\left(\left.\omega\right|_{n}\right)^{\star} \mid}\right| . ~ . ~}^{\text {. }}\right.
$$

These functions converge uniformly on $\Omega$ with an order of convergence $O\left(\beta^{n \epsilon}\right)$, where on $\Omega$ we consider the metric $d_{\beta}$ given in Section 2.

Definition. The scaling function $R: \Omega \rightarrow \operatorname{int}(\Delta)$ is defined by

$$
R(\omega):=\lim _{n \rightarrow \infty} R_{n}(\omega)
$$

With the metric $d_{\beta}$, the scaling function is Hölder continuous with exponent $\epsilon$.
Theorem (Sullivan). Two $\mathcal{C}^{k+\epsilon}$-regular Cantor sets are $\mathcal{C}^{k+\epsilon}$-conjugated if and only if they have the same scaling function.

As an application, we obtain the following theorem.
Theorem 13. The system $\left(C_{p},\left\{f_{p, 0}, f_{p, 1}\right\}\right)$ and $\left(A_{2^{-p}},\left\{2^{-p} x, 2^{-p} x+\left(1-2^{-p}\right)\right\}\right)$ are $\mathcal{C}^{1+1 / p_{-}}$ conjugate. In particular, $C_{p}$ is $\mathcal{C}^{1+1 / p}$-diffeomorphic to $A_{2^{-p}}$.
Proof. By Sullivan's Theorem we must verify that both scaling functions coincide. Since $A_{2-p}$ has contraction ratio $2^{-p}$, it follows that its scaling function is

$$
R(\alpha)=\left(\frac{1}{2^{p}}, \frac{2^{p}-2}{2^{p}}, \frac{1}{2^{p}}\right)
$$

Let us see that this is also the scaling function of $C_{p}$. Recall that for $\omega \in \Omega$,

$$
\left(\frac{1}{2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)+1}\right)^{p} \frac{2^{p}}{2^{p}-2} \leq\left|I_{\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)}^{n}\right| \leq \frac{2^{p}}{2^{p}-2}\left(\frac{1}{2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)}\right)^{p} .
$$

Then, by the identity $\ell\left(\left(\left.\omega\right|_{n}\right)^{\star} i\right)=2 \ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)+i$ for $i=0,1$, we obtain

$$
\begin{aligned}
\frac{\left|I_{\left(\left.\omega\right|_{n}\right)^{\star} i}\right|}{\mid I_{\left(\left.\omega\right|_{n}\right)^{\star} \mid}} & \leq\left(\frac{2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)+1}{2^{n+1}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star} i\right)}\right)^{p} \\
& \leq \frac{1}{2^{p}}\left(1+\frac{1}{2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)}\right)^{p} \longrightarrow \frac{1}{2^{p}},
\end{aligned}
$$

with a similar lower bound, thus $\left|I_{\left(\left.\omega\right|_{n}\right)^{\star} i}\right| /\left|I_{\left(\left.\omega\right|_{n}\right)^{\star}}\right| \rightarrow 1 / 2^{p}$. Since the sum of the coordinates of the scaling function is 1 , we obtain the coincidence of these functions.

The scaling function also exists if weaker conditions on the derivatives of the functions are required. For example, if they satisfy the Dini condition (see for example [FJ99]), or more generally, a bounded distortion property. We finish this section illustrating that, despite the fact that the functions of the IFS are only $\mathcal{C}^{1}$, the scaling function may exist, and moreover, it can be a Hölder continuous function.

Example 14. The Cantor set $C_{p, 1}$ associated to the sequence $\left\{(\log n) / n^{p}\right\}$ satisfies:

1) It is the attractor of an $\operatorname{IFS}\left\{f_{0}, f_{1}\right\}$ with $f_{i} \in \mathcal{C}^{1}$.
2) The derivatives are not $\epsilon$-Hölder continuous for any $\epsilon>0$ (actually, they do not satisfy the bounded distortion property).
3) Its scaling function is constant, with value $\left(\frac{1}{2^{p}}, \frac{2^{p}-2}{2^{p}}, \frac{1}{2^{p}}\right)$; in particular this function is $\epsilon$-Hölder continuous, for any $\epsilon>0$.
Proof. 1) First, for all $0 \leq l<2^{k}, k \geq 1$ we have

$$
\begin{equation*}
\frac{1}{\left(2^{k}+l+1\right)^{p}}\left(\tilde{c}_{p}+c_{p} \log \left(2^{k}+l\right)\right) \leq\left|I_{l}^{k}\right| \leq\left(\tilde{c}_{p}+c_{p} \log \left(2^{k}+l+1\right)\right) \frac{1}{\left(2^{k}+l\right)^{p}}, \tag{4.1}
\end{equation*}
$$

where $c_{p}=\sum_{j \geq 0} \frac{1}{2^{(p-1) j}}$ and $\tilde{c}_{p}=\sum_{j \geq 0} \frac{\log 2^{j}}{2^{(p-1) j}}$; this is obtained in the same way as the bounds of Lemma 1 .

Now we show that $C_{p, 1}$ is the attractor of a system $\left\{f_{0}, f_{1}\right\}$ with continuous derivatives such that $f_{\omega}(I)=I_{\ell(\omega)}^{k}$ for all $\omega \in \Omega_{k}, k \geq 1$. Given $\omega \in \Omega_{k}$, by estimate (4.1) we have that

$$
\lim _{n \rightarrow \infty} \frac{\left|I_{\ell(i(\omega \bar{u}) \mid n}^{n+1}\right|}{\left|I_{\ell((\omega \bar{u}) \mid n)}^{n}\right|}=\left(\frac{2^{k}+\ell(\omega)+u}{2^{k+1}+i 2^{k}+\ell(\omega)+u}\right)^{p}, \quad \text { for } u=0,1 .
$$

By Proposition 5, this limit gives the values of the derivatives at the endpoints. Notice that these are the same values than the one obtained in the $C_{p}$ case; in particular, they coincide at the endpoints of any gap (Lemma 7 (b)).

As before we must subtract some area over each gap, which can be done with triangles because the same bounds as in Lemma 11 hold.
2) It was shown in [GMS07] that $\operatorname{dim}_{H} C_{p, 1}=1 / p$ and moreover, that

$$
\mathcal{H}^{1 / p}\left(C_{p, 1}\right)=+\infty,
$$

whence this set cannot be the attractor of a system whose functions have $\epsilon$-Hölder continuous derivatives, for any $\varepsilon>0$ (neither can the derivatives satisfy the bounded distortion property).
3) Given $\omega \in \Omega$ we have

$$
\frac{\left|I_{\left(\left.\omega\right|_{n}\right)^{\star} i}\right|}{\left|I_{\left(\left.\omega\right|_{n} \star\right.}{ }^{\star}\right|} \leq\left(\frac{2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)+1}{2^{n+1}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star} i\right)}\right)^{p} \cdot \frac{\tilde{c}_{p}+c_{p} \log \left(2^{n+1}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star} i\right)+1\right)}{\tilde{c}_{p}+c_{p} \log \left(2^{n}+\ell\left(\left(\left.\omega\right|_{n}\right)^{\star}\right)\right)} \longrightarrow \frac{1}{2^{p}},
$$

since one can show that the second factor in the product goes to 1 . The lower bound is similar. Hence the scaling function is $R(\omega)=\left(\frac{1}{2^{p}}, \frac{2^{p}-2}{2^{p}}, \frac{1}{2^{p}}\right)$ for all $\omega \in \Omega$.
Remark. The scaling functions of ( $C_{p},\left\{f_{p, 1}, f_{p, 0}\right\}$ ) and ( $C_{p, 1},\left\{f_{0}, f_{1}\right\}$ ) coincide by item 3) above. Nevertheless these Cantor sets are not even Lipschitz conjugate in view of 1). This shows that in Sullivan's Theorem the regularity hypothesis cannot be weakened to $\mathcal{C}^{1}$.

## 5. Sums and convolutions

In this section we provide results on sums of two Cantor sets in the family $\left\{C_{p}\right\}$ and on the convolution of measures supported on these sets. We begin giving an estimate of the thickness of $C_{p}$, which is used to obtain conditions so that the sumset has nonempty interior. Subsequently, for a given compact $K \subset \mathbb{R}$, we adapt a result of Peres and Schlag [PS00] to study the size of the set of parameters where the convolution measure $\left.\left.\mathcal{H}^{1 / p}\right|_{C_{p}} * \mathcal{H}^{1 / p^{\prime}}\right|_{C_{p^{\prime}}}$ is not absolutely continuous (Corollary 18) and also where the formula $\operatorname{dim}\left(K+C_{p}\right)=$ $\min \left\{\operatorname{dim} K+\operatorname{dim} C_{p}, 1\right\}$ does not hold.

Let $L$ be a bounded gap of a Cantor set $C$. A bridge $B$ of $L$ is a maximal interval that has a common endpoint with $L$ and does not intersect any gap whose length is at least that of $L$. We say that $(B, L)$ is a bridge/gap pair of $C$. The thickness of $C$ is defined by

$$
\tau(C)=\inf \left\{\frac{|B|}{|L|}:(B, L) \text { is a bridge/gap pair }\right\}
$$

An important consequence of Newhouse's gap lemma is that the sum $C_{1}+C_{2}$ of two Cantor sets is a finite union of intervals if $\tau\left(C_{1}\right) \cdot \tau\left(C_{2}\right) \geq 1$ (see [PT93]). Moreover, if none of the translates of either of the Cantor sets are contained in a (bounded) gap of the other, then $C_{1}+C_{2}$ is an interval.

In the classical case we have $\tau\left(A_{r}\right)=2 r /(1-2 r)$. If $2^{-p}$ takes the place of $r$ one would expect that $C_{p}+C_{p^{\prime}}$ be an interval when $\frac{1}{2^{p}-2} \frac{1}{2^{p^{\prime}}-2} \geq 1$. But the thickness of $C_{p}$ is bigger than expected because of the nonlinearity of the set. Nevertheless, a slightly weaker result can be attained if we consider a local version of thickness instead.

Given $x \in C$ let $\omega \in \Omega$ be such that $\pi(\omega)=x$. Then the Cantor sets $C_{x}^{k}:=C \cap I_{\ell\left(\omega^{k}\right)}^{k}$ decrease to $\{x\}$ as $k \rightarrow \infty$. The local thickness of $C$ at $x$ is

$$
\tau_{\mathrm{loc}}(C, x):=\varlimsup_{k \rightarrow \infty} \tau\left(C_{x}^{k}\right)
$$

It can be shown, following the proof of Newhouse's lemma, that if $x_{1} \in C_{1}$ and $x_{2} \in C_{2}$ are such that $\tau_{\text {loc }}\left(C_{1}, x_{1}\right) \cdot \tau_{\text {loc }}\left(C_{2}, x_{2}\right)>1$, then $C_{1}+C_{2}$ contains a nonempty open interval. Moreover, if

$$
\inf _{x \in C_{1}, y \in C_{2}}\left\{\tau_{\text {loc }}\left(C_{1}, x\right) \cdot \tau_{\text {loc }}\left(C_{2}, y\right)\right\}>1
$$

then $C_{1}+C_{2}$ is a finite union of intervals.
In general, regular Cantor sets have constant local thickness (see [PT93]). In our case it is easy to compute this value.

Proposition 15. We have

$$
\begin{equation*}
\frac{1}{2^{p}} \frac{1}{2^{p}-2} \leq \tau\left(C_{p}\right) \leq\left(\frac{2}{3}\right)^{p} \frac{1}{2^{p}-2} \tag{5.1}
\end{equation*}
$$

Moreover

$$
\begin{equation*}
\tau_{l o c}\left(C_{p}\right)=\frac{1}{2^{p}-2} \tag{5.2}
\end{equation*}
$$

Proof. Since lengths of bounded gaps of $C_{p}$ are lexicographically decreasing, the bridge for $L_{2^{k}+j}$ is the closed interval of the $k+1$-step which is at its right, that is $I_{2 j+1}^{k+1}$. Therefore inequalities (2.4) implies

$$
\begin{equation*}
\frac{1}{2^{p}-2}\left(\frac{2^{k}+j}{2^{k}+j+1}\right)^{p} \leq \frac{\left|I_{2 j+1}^{k+1}\right|}{\left|L_{2^{k}+j}\right|} \leq \frac{1}{2^{p}-2}\left(\frac{2^{k}+j}{2^{k}+j+1 / 2}\right)^{p} . \tag{5.3}
\end{equation*}
$$

Thus the bounds for the quotient bridge/gap increase to $1 /\left(2^{p}-2\right)$ as $k$ and $j$ increase. From this, for $k=j=0$, the first inequality in (5.3) gives a lower bound for all quotients bridge/gap and therefore the lower bound in (5.1). Moreover, $k=j=0$ gives the smallest of all upper bounds in (5.3), that is the second inequality in (5.1).

Note that for the local thickness every bridge/gap pair of $C_{p, x}^{k}$ is one of $C_{p}$; hence by (5.3) we have

$$
\frac{1}{2^{p}-2}\left(\frac{2^{k}}{2^{k}+1}\right)^{p} \leq \tau\left(C_{p, x}^{k}\right) \leq \frac{1}{2^{p}-2}\left(\frac{2^{k+1}-1}{2^{k+1}-1 / 2}\right)^{p}
$$

and (5.2) follows letting $k \rightarrow \infty$.
As a consequence of the above we have the following result.
Corollary 16. For $\frac{1}{2^{p}\left(2^{p}-2\right)} \frac{1}{2^{q}\left(2^{q}-2\right)} \geq 1$ the set $C_{p}+C_{q}$ is an interval. Moreover, if $\frac{1}{2^{p}-2}$. $\frac{1}{2^{q}-2}>1$ then $C_{p}+C_{q}$ is a finite union of intervals.

Finally we concentrate on the measure theoretic results of the dimension of $C_{p}+C_{q}$ and the corresponding problem of convolution measures given in the introduction.

Indeed we will work with a more general parametric family. Let $\left\{C_{p, q}\right\}_{p>1, q \in \mathbb{R}}$ be the family of Cantor sets associated to the sequence $\left\{\log ^{q} n / n^{p}\right\}_{n}$ (the term $n=1$ is defined as 1). Notice that $\operatorname{dim} C_{p, q}=1 / p$; see [GMS07]. We regard $q$ as a $\mathcal{C}^{\infty}$ function of $p$ on $(1,+\infty)$, so from now onwards $\left\{C_{p, q}\right\}_{p}$ is an uniparametric family with $q$ depending on $p$.

Recall that a finite measure $\eta$ with compact support is a Frostman measure with exponent $s>0$ if

$$
\eta\left(B_{r}(x)\right) \leq C r^{s}, \quad \text { for } x \in \mathbb{R} \text { and } r>0
$$

By Frostman's Lemma, given a compact set $K$ and $s<\operatorname{dim} K$ there is a Frostman measure supported on $K$ with exponent $s$; see Mattila [Mat95].

Let $\mu_{0}$ denote the uniform product measure on $\Omega=\{0,1\}^{\mathbb{N}}$. A probability measure on $C_{p, q}$ is defined by $v_{p, q}=\mu_{0} \circ \Gamma_{p, q}^{-1}$, where $\Gamma_{p, q}: \Omega \rightarrow C_{p, q}$ is the projection defined in (2.6). Note that for $q \equiv 0$, we have $v_{p}=v_{p, 0}$, where $v_{p}$ is the invariant measure of the regular i.f.s. that generates $C_{p}$ with weights $(1 / 2,1 / 2)$. Also this is a Frostman measure with exponent $1 / p$; see [Fal97], Theorem 5.3.

The main theorems of this part are stated below. Let us denote with $\nu \in L^{2}\left(\nu \notin L^{2}\right)$ the fact that the measure $\nu$ has (does not have) a density in $L^{2}(\mathbb{R})$.

Theorem 17. Let $\eta$ be a Frostman measure with exponent $s \in(0,1)$ and let $\bar{p}$ be such that $s+1 / \bar{p}=1$. Given $J \subset(1, \bar{p})$ a closed interval, $J=\left[p_{0}, p_{1}\right]$ we have

$$
\begin{equation*}
\operatorname{dim}\left(\left\{p \in J: \eta * v_{p, q} \notin L^{2}\right\}\right) \leq 2-\left(s+\frac{1}{p_{1}}\right) . \tag{5.4}
\end{equation*}
$$

In particular, the measure $\eta * v_{p, q}$ has a density in $L^{2}$ for $\mathcal{L}$-a.e. $p \in(1, \bar{p})$.
Let us denote by $\mu \ll \nu$ if $\mu$ is absolutely continuous with respect to $\nu$.
Corollary 18. For a fixed $p^{\prime}>1$ we have $v_{p} * v_{p^{\prime}} \ll \mathcal{L}\left(\left.\left.\mathcal{H}^{1 / p}\right|_{C_{p}} * \mathcal{H}^{1 / p^{\prime}}\right|_{C_{p^{\prime}}} \ll \mathcal{L}\right)$ with density in $L^{2}(\mathbb{R})$ for $\mathcal{L}$-a.e. $p$ such that $\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}>1$.

Remark. The convolution $v_{p^{\prime}} * v_{p}$ is singular with respect to $\mathcal{L}$ if $\operatorname{dim} C_{p}+\operatorname{dim} C_{p^{\prime}}<1$, since $\operatorname{supp}\left(v_{p} * v_{p^{\prime}}\right)=C_{p}+C_{p^{\prime}}$.

For sumsets we have the following result, that is analogous to Theorem 5.12 for homogeneous Cantor sets in [PS00].

Theorem 19. Let $K \subset \mathbb{R}$ be a compact set and $J=\left[p_{0}, p_{1}\right] \subset(1,+\infty)$. Then

$$
\begin{equation*}
\operatorname{dim}\left\{p \in J: \operatorname{dim}\left(K+C_{p, q}\right)<\operatorname{dim} K+\operatorname{dim} C_{p, q}\right\} \leq \operatorname{dim} K+\operatorname{dim} C_{p_{0}, q\left(p_{0}\right)} \tag{5.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{dim}\left\{p \in J: \mathcal{H}^{1}\left(K+C_{p, q}\right)=0\right\} \leq 2-\left(\operatorname{dim} K+\operatorname{dim} C_{p_{1}, q\left(p_{1}\right)}\right) . \tag{5.6}
\end{equation*}
$$

Note that (5.6) follows from (5.4) choosing $s<\operatorname{dim} K$, taking a Frostman measure on $K$ with exponent $s$ and then letting $s \nearrow \operatorname{dim} K$.
5.1. Proof of Theorems 17 and 19. These theorems are a consequence of a projection theorem of Peres and Schlag [PS00] (see also [PSS00]) and their proofs follow closely that of Theorem 5.12 in that paper. We need to state a one dimensional version of the projection theorem, and for this we may introduce some definitions and notation.

Definition. The Sobolev dimension of a finite measure on $\mathbb{R}^{n}$ with compact support is defined by

$$
\operatorname{dim}_{s}(\nu)=\sup \left\{\alpha: \int(1+|x|)^{\alpha-1}|\hat{\nu}(x)|^{2} d x<+\infty\right\} .
$$

The properties of Sobolev dimension that we will use are stated below; see Mattila [Mat04], Proposition 5.1.

Proposition 20. Let $\nu$ be finite measure on $\mathbb{R}^{n}$ with compact support.

1. If $0 \leq \operatorname{dim}_{s} \nu \leq n$, then $\operatorname{dim}_{s} \nu \leq \operatorname{dim}($ supp $\nu)$.
2. If $\operatorname{dim}_{s} \nu>n$, then $\nu \in L^{2}\left(\mathbb{R}^{n}\right)$.

The general setting of the projection theorem consists in a compact metric space $(\Theta, d)$ together with a continuous map $\Pi: L \times \Theta \rightarrow \mathbb{R}$, where $L \subset \mathbb{R}$ is an open interval. For this map it is assumed that for any compact $J \subset L$ and $m \in \mathbb{N}$ there exists $c_{m, J}$ such that

$$
\left|\frac{d^{m}}{d p^{m}} \Pi(p, \omega)\right| \leq c_{m, J}
$$

for every $p \in J$ and $\omega \in \Theta$. The functions $\Pi_{p}(\cdot):=\Pi(p, \cdot)$ can be seen as a family of projections parameterized by $p$. Given a finite measure $\mu$ on $\Theta$, consider the family of projected measures $\nu_{p}=\mu \circ \Pi_{p}^{-1}$. Peres and Schlag [PS00] related the smoothness of the projected measures $\nu_{p}$ to the $\alpha$-energy of the measure $\mu$, defined by $\mathcal{E}_{\alpha}(\mu)=\int_{\Theta} \int_{\Theta} \frac{d \mu(\omega) d \mu(\tau)}{d(\omega, \tau)^{\alpha}}$. For this it is crucial that $\Pi$ verifies the transversality condition, which is a kind of non degeneracy condition.

Definition. For any distinct $\omega_{1}, \omega_{2} \in \Theta$ and $\lambda \in J$ let

$$
\Phi_{\omega_{1}, \omega_{2}}(\lambda)=\frac{\Pi\left(\lambda, \omega_{1}\right)-\Pi\left(\lambda, \omega_{2}\right)}{d\left(\omega_{1}, \omega_{2}\right)} .
$$

For any $\beta \in[0,1)$ we say that $J$ is an interval of transversality of order $\beta$ for $\Pi$ if there is a constant $C_{\beta}$ such that condition

$$
\left|\Phi_{\omega_{1}, \omega_{2}}(\lambda)\right| \leq C_{\beta} d\left(\omega_{1}, \omega_{2}\right)^{\beta} \quad \forall \lambda \in J, \forall \omega_{1}, \omega_{2} \in \Theta
$$

implies

$$
\begin{equation*}
\left|\frac{d}{d \lambda} \Phi_{\omega_{1}, \omega_{2}}(\lambda)\right| \geq C_{\beta} d\left(\omega_{1}, \omega_{2}\right)^{\beta} . \tag{5.7}
\end{equation*}
$$

In addition, we say that $\Pi$ is regular on $J$ if under the same condition and for all positive integer $m$ there is a constant $C_{\beta, m}$ such that

$$
\begin{equation*}
\left|\frac{d^{m}}{d \lambda^{m}} \Phi_{\lambda}\left(\omega_{1}, \omega_{2}\right)\right| \leq C_{\beta, m} d\left(\omega_{1}, \omega_{2}\right)^{-\beta m} \tag{5.8}
\end{equation*}
$$

Next we state (incompletely) the Peres-Schlag projection theorem.
Theorem 21 ([PS00], Theorem 2.8). Let $\Theta, J$ and $\Pi$ be as above. Suppose that $J$ is an interval of transversality of order $\beta$ for $\Pi$ for some $\beta \in(0,1]$ and that $\Pi$ is regular on J. Let $\mu$ be a finite measure on $\Theta$ with finite $\alpha$-energy for some $\alpha>0$. Then, for any $\sigma \in(0, \alpha]$ we have

$$
\begin{equation*}
\operatorname{dim}\left\{p \in J: \operatorname{dim}_{s}\left(\nu_{p}\right) \leq \sigma\right\} \leq 1+\sigma-\frac{\alpha}{1+a_{0} \beta}, \tag{5.9}
\end{equation*}
$$

where $a_{0}$ is some absolute constant. Moreover, for any $\sigma \in(0, \alpha-3 \beta]$ we have

$$
\begin{equation*}
\operatorname{dim}\left\{p \in J: \operatorname{dim}_{s}\left(\nu_{p}\right)<\sigma\right\} \leq \sigma \tag{5.10}
\end{equation*}
$$

Now we apply the above to prove Theorems 17 and 19. For notational convenience we state some preliminary lemmas in a very general setting.

Let $\left\{\Lambda_{p}\right\}_{p \in L}$ be a family of Cantor sets, where $L$ is an open interval. It is assumed that $\operatorname{dim} \Lambda_{p}$ is a decreasing function of $p$. The code map from $\Omega=\{0,1\}^{\mathbb{N}}$ to $\Lambda_{p}$ is denoted $\pi_{p}$; we may assume that $\pi_{\omega} \in \mathcal{C}^{\infty}(J)$ for each $\omega \in \Omega$, where $\pi_{\omega}(p):=\pi_{p}(\omega)$. Now fix a compact set $K \subset \mathbb{R}$ and define $\Theta=K \times \Omega$. The projection map $\Pi: L \times \Theta \rightarrow \mathbb{R}$ is defined by

$$
\Pi(p, x, \omega)=x+\pi_{p}(\omega)
$$

Let $\eta$ be a Frostman measure on $K$ with exponent $s$ (sufficiently close to $\operatorname{dim} K$ ) and consider on the space $\Theta$ the measure $\mu=\mu_{0} \times \eta$, with $\mu_{0}$ the uniform product measure on $\Omega$.

Given $J=\left[p_{0}, p_{1}\right] \subset L$ we define a metric on $\Omega$ by

$$
\tilde{d}(\omega, \tau)=\left\{\begin{array}{cc}
d_{k}, & \text { if }|\omega \wedge \tau|=k \\
0, & \text { if } \omega=\tau
\end{array}\right.
$$

where $d_{k}=\max _{|\gamma|=k}\left|I_{\gamma}^{p_{0}}\right|$, with $I_{\gamma}^{p}$ the corresponding interval of the $k$-step of $\Lambda_{p}$. Thus, the metric on $\Theta$ is

$$
d((x, \omega),(y, \tau))=|x-y|+\tilde{d}(\omega, \tau)
$$

Remark 22. It can be verified directly from the definition that the projected measure $\nu_{p}=$ $\mu \circ \Pi_{p}^{-1}$ coincides with the convolution $\eta * v_{p}$.

Let us begin with the energy estimate for $\mu$.
Lemma 23. Let $J=\left[p_{0}, p_{1}\right] \subset(1, \infty)$. Then the $\alpha$-energy of $\mu$ is finite provided $\alpha<$ $s+\operatorname{dim} \Lambda_{p_{0}}$.

Proof. Note that

$$
\begin{aligned}
\mathcal{E}_{\alpha}(\mu) & =\int_{\Omega} \int_{\Omega} \int_{K} \int_{K} \frac{d \eta(x) d \eta(y) d \mu_{0}(\omega) d \mu_{0}(\tau)}{(|x-y|+\tilde{d}(\omega, \tau))^{\alpha}} \\
& =\int_{K} \int_{K} \sum_{k \geq 0} \frac{1}{2^{k}} \frac{d \eta(x) d \eta(y)}{\left(|x-y|+d_{k}\right)^{\alpha}} \\
& =\int_{K} \int_{K} \sum_{k:|x-y| \leq d_{k}}+\int_{K} \int_{K} \sum_{k:|x-y|>d_{k}}=I+I I .
\end{aligned}
$$

We are going to estimate $I$ and $I I$ separately. We have

$$
I \leq \sum_{k \geq 0} \frac{1}{2^{k}} \frac{1}{d_{k}^{\alpha}}(\eta \times \eta)\left\{|x-y| \leq d_{k}\right\} \leq c \sum_{k \geq 0} \frac{1}{2^{k}} \frac{1}{d_{k}^{\alpha-s}},
$$

where the last inequality holds since $\eta$ is a Frostman measure with exponent $s$. Then $I<+\infty$ because the last sum is bounded by a convergent geometrical series. This obtained in the following way. Choose $\varepsilon>0$ such that $t:=\alpha-s+\varepsilon<\operatorname{dim} \Lambda_{p_{0}}$. Note that $2^{k} d_{k}^{t} \nearrow+\infty$; this is because this quantity is an upper bound for the $t$-dimensional cover of $\Lambda_{p_{0}}$ with the intervals of the $k$-step. Then $2^{k} d_{k}^{t}>1$ for all big enough $k$, or equivalently, $\left(2^{k} d_{k}^{\alpha-s}\right)^{-1}<2^{k-\varepsilon} \frac{-\varepsilon}{\alpha-s+\varepsilon}$.

For the second term, with $t$ as above, we have $|x-y|>d_{k}>2^{-k / t}$. If $\kappa(x, y)$ is the minimum $k$ which verifies this inequality, that is, $\kappa(x, y)=\left\lfloor-\log |x-y| / \log 2^{1 / t}\right\rfloor$, then

$$
I I \leq c^{\prime} \int_{K} \int_{K} \frac{1}{2^{\kappa(x, y)}} \frac{d \eta(x) d \eta(y)}{|x-y|^{\alpha}} \leq c^{\prime \prime} \int_{K} \int_{K} \frac{d \eta(x) d \eta(y)}{|x-y|^{\alpha-t}}<+\infty
$$

the last inequality is because $\alpha-t=s-\varepsilon$ is smaller than the exponent of $\eta$ (see [Mat95], chapter 8).

A sufficient condition for transversality is given below.
Lemma 24. The closed interval $J \subset(1,+\infty)$ is of transversality of order $\beta$ for $\Pi$ provided there is a constant $c_{\beta}$ such that

$$
\begin{equation*}
\left|\pi_{\omega}^{\prime}(p)-\pi_{\tau}^{\prime}(p)\right| \geq c_{\beta} d_{k}^{\beta+1}, \quad \text { if }|\omega \wedge \tau|=k \tag{5.11}
\end{equation*}
$$

for all $\omega, \tau \in \Omega, p \in J$. Moreover, $\Pi$ is regular on $J$ if

$$
\begin{equation*}
\left|\frac{d^{m}}{d p^{m}} \pi_{\omega}(p)-\frac{d^{m}}{d p^{m}} \pi_{\tau}(p)\right| \leq c_{\beta, m} d_{k}^{1-\beta m} \tag{5.12}
\end{equation*}
$$

for some constant $c_{\beta, m}$.
Proof. Suppose

$$
\begin{equation*}
\left|\Phi_{\omega_{1}, \omega_{2}}(p)\right| \leq C_{\beta} d\left(\omega_{1}, \omega_{2}\right)^{\beta}, \text { for all } \omega_{1}, \omega_{2} \in \Theta \tag{5.13}
\end{equation*}
$$

for some small enough constant $C_{\beta}$. Now fix $\omega_{1}=(x, \omega), \omega_{2}=(y, \tau) \in \Theta$. We may assume $k=|\omega \wedge \tau| \neq 0$, since otherwise what follows is trivial. Let $r=d((x, \omega),(y, \tau))=|x-y|+d_{k}$. Observe that transversality and regularity follow easily from (5.11) and (5.12) if we can show that $r \approx d_{k}$. This is a consequence of (5.13). In fact, if $|x-y| \geq 2 d_{k}$ then $u=|x-y| / d_{k}>2$, which implies

$$
\left|\Phi_{\omega_{1}, \omega_{2}}(p)\right| \geq \frac{|x-y|-d_{k}}{|x-y|+d_{k}}=\frac{u-1}{u+1} \geq C>0
$$

This contradicts (5.13) if $C_{\beta}<C$.
Proof of Theorem 17. Recall that $a_{n}^{p}=(\log n)^{q} / n^{p}$, where $q=q(p) \in \mathcal{C}^{\infty}(J)$. Firstly note that $\Gamma_{\omega} \in \mathcal{C}^{\infty}((1,+\infty))$ for each $\omega$. In fact, since any point in a Cantor set is (can be described as) the sum of the length of all gaps which lie to its left, we obtain $\Gamma_{p}(\omega)=\sum_{n \geq 1} a_{n}(\omega)$, where $a_{n}(\omega)=a_{n}^{p}$ if the gap $L_{n}$ is to the left of $\Gamma_{p}(\omega)$ and $a_{n}(\omega)=0$ otherwise. Also, for each $p$ and $m$ we have that

$$
b_{n}^{p, m}=\frac{d^{m} a_{n}}{d p^{m}} \approx \frac{(\log n)^{q+m}}{n^{p}},
$$

and therefore one can associate to $\left\{b_{n}^{p, m}\right\}_{n}$ a Cantor set whose intervals have lengths equivalent to those of $C_{p, q+m}$. In particular, Lemma 1 (or its proof) implies

$$
\begin{equation*}
\frac{k^{q+m}}{2^{k p}} c_{p} \leq\left|\frac{d^{m}}{d p^{m}} \Gamma_{\omega}(p)-\frac{d^{m}}{d p^{m}} \Gamma_{\tau}(p)\right| \leq c_{p}^{\prime} \frac{k^{q+m}+1}{2^{k p}}, \tag{5.14}
\end{equation*}
$$

where $k=|\omega \wedge \tau|$ and $c_{p}$ and $c_{p}^{\prime}$ are uniformly bounded on compact subsets of $(1,+\infty)$.
Transversality holds in smaller subintervals of J . That is, given $\beta \in(0,1)$ decompose $J=\bigcup_{i=1}^{N} J_{i}$, with $J_{i}=\left[p_{i}, p_{i+1}\right]$, so that

$$
\beta>\frac{p_{i+1}}{p_{i}}-1 .
$$

Choose $\varepsilon>0$ such that $\beta-\varepsilon$ satisfies the above inequality. Then, letting $|\omega \wedge \tau|=k$ and $\tilde{q}=\min _{p \in I}\{q(p)\}$, we have from (5.14)

$$
\left|\Gamma_{\omega}^{\prime}(p)-\Gamma_{\tau}^{\prime}(p)\right| \geq c_{I} \frac{k^{\tilde{q}+1}}{2^{k p_{i+1}}}>c_{I} \frac{k^{\tilde{q}+1} 2^{k p_{i} \varepsilon}}{2^{k p_{i}(\beta+1)}} \geq c_{I, \beta} \frac{k^{q\left(p_{i}\right)}+1}{2^{k p_{i}(\beta+1)}} \geq c_{I, \beta}^{\prime} d_{k}^{\beta+1}
$$

the last inequality follows from Lemma 1. Hence each $J_{i}$ is an interval of $\beta$ transversality by Lemma 24. Regularity can be verified from (5.14) as well.

Since on $J_{i}$ the $\alpha$-energy of $\mu$ is finite provided $\alpha<s+1 / p_{i}$, from Remark 22 and (5.9) in Theorem 21 we obtain

$$
\begin{aligned}
\operatorname{dim}\left(\left\{p \in J_{i}: \eta * v_{p, q} \notin L^{2}\right\}\right) & \leq \operatorname{dim}\left(\left\{p \in J_{i}: \operatorname{dim}_{s}\left(\eta * v_{p}\right) \leq 1\right\}\right) \\
& \leq 2-\frac{s+1 / p_{i}}{1+a_{0} \beta} \leq 2-\frac{s+1 / p_{1}}{1+a_{0} \beta}
\end{aligned}
$$

and (5.4) follows letting $\beta \rightarrow 0$.
To prove (5.5) in Theorem 19 we proceed as in the above proof but we use (5.10) in Theorem 21 instead. Details are omitted.

## Acknowledgments

The author expresses his gratitude to his advisors, Ursula Molter and Roberto Scotto, for their valuable suggestions and for reading the manuscript. He also thanks Esa Järvenpää for suggesting the use of the Peres-Schalg projection theorem instead of the techniques of Peres and Solomyak [PS98].
